ART-UNIT: 272

PRIMARY-EXAMINER: Matar; Ahmad F.

ABSTRACT:

A system and method for processing telephone calls and providing enhanced services is presented. The call processing system includes a network control processor for controlling the processing and routing of the calls and for providing enhanced features, and a matrix switch for routing calls from an originating location to a terminating location. Operator consoles can be included to provide operator assistance to the caller. The network control processor comprises a central message processor that receives call data, determines the type of call, determines the processing required, and determines whether operator assistance is required. A call route distributor allocates an operator console to the call if required. A billing server is used to track billing information for the call while it is in progress. A database server is provided for database look-ups and storage. The call processing system also includes a validation system, a billing system, a distribution system, and a fraud detection and prevention system. The validation system is used to validate call information to determine whether the call can be placed. The billing system determines rates for calls and calculates the cost of completed calls. The distribution system distributes changes that are made to a master database to the appropriate slave database. The fraud detection and prevention system monitors originating and in-process calls to detect and possibly prevent possible fraudulent uses of phone services and systems. A client interface is provided to facilitate communications among applications and DEF records are used to define specific call

processing actions.

ART-UNIT: 268

PRIMARY-EXAMINER: Bost; Dwayne

ASSISTANT-EXAMINER: Trost; William G.

ABSTRACT:

A person communications internetworking provides a network subscriber with the ability to remotely control the receipt and delivery of wireless and wireline voice and text messages. The network operates as an interfaces between various wireless and wireline networks, and also performs media translation, where necessary. The subscriber's message receipt and delivery options are maintained in a database which the subscriber may access by wireless or wireline communications to update the options programmed in the database. The subscriber may be provided with CallCommand service which provides real-time control of voice calls while using a wireless data terminal or PDA.

ART-UNIT: 274

PRIMARY-EXAMINER: Cumming; William

ABSTRACT:

A mobile satellite system includes a network engineering/systems engineering (NE/SE) system. The NE/SE performs the processes of comparing expected traffic loads with capability and availability of space and ground resources in the mobile satellite system, formulating tactical plans to maximize available resources of the satellite, and producing frequency plans for different geographical regions and defining circuit pools for different groups of users of the METs. The NE/SE also performs the processes of defining contingency plans for failure situations, such as failure in the satellite or a ground-based equipment outage, configuring the mobile satellite system including logical resources and physical components generating logical and

physical configurations, the logical and physical configurations designed to expand the mobile satellite system capacity for increases in traffic demand, while also supporting new features and services of the mobile satellite system. The NE/SE further configures communication paths to external organizations operatively connected to the mobile satellite system, and tracks logistics of network additions to the mobile satellite system via generation of work orders.

L4: Entry 1 of 1

File: USPT

Nov 20, 1984

DOCUMENT-IDENTIFIER: US 4484306 A

TITLE: Method and apparatus for controlling access in a data transmission system

Application Filing Date (1):
19820322

Detailed Description Text (3):

The data processing system 10 further includes a communication link or transmission means 18 for providing communication between the host computer 14 and the user terminal 16. In the present embodiment, the user terminal 16 is a remote terminal located at a facility away from the computer apparatus 14. The communication link or transmission means 18 comprises an originate or terminal modem 20 and an answer or computer modem 22, which convert the digital data and control signals from the user terminal 16 and host computer 14, respectively, into suitable analog signals which are then modulated for passage between the modems 20 and 22 via a suitable communications means 24, such as microwave transmission, telephone line or any other conventional communication system. The modems 20 and 22 also receive the modulated signals from, for example, the telephone line generally designated 24, demodulate them and convert them back to digital signals which are then forwarded to the user terminal 16 and host computer 14, respectively. The modems 20 and 22 are of a standard type which are well known in the art and commercially available from various manufacturers. A detailed description of the structure and operation of the modems 20 and 22 is readily available from the manufacturers. It will also be appreciated by those skilled in the art that any other suitable transmission means may be substituted for the modems 20 and 22 and telephone system 24 as shown on FIG. 1 without departing from the scope of the present invention as long as appropriate interfacing is employed.

Detailed Description Text (29):

As a further enhancement to the above-described access control system 12, the accessor computer of each individual accessor apparatus 32 may be preprogrammed to maintain in storage (PROM 72) a unique identifier such as a serial number or ID number. Correspondingly, the controller computer 44 may be programmed to query or pole the accessor computer 56 (either before or after the transmission and receipt of the random question), to determine exactly which accessor apparatus 32 is attempting to access the host computer 14. The identifier information from the accessor apparatus 32 could then be transferred to the host computer 14 for various further uses. One such use of the identifier information would be to maintain a log of the total computer time utilized by a particular accessor apparatus 32 (i.e., the individual controlling the particular accessor apparatus) for billing or other record keeping purposes. Another use of such identifier information would be to allow the host computer 14 to regulate the amount of computer time to be allocated to a particular individual, for example on a weekly or monthly basis or to regulate the information available to the particular operator. Another use of such identifier information is to selectively allow or disallow certain accessor apparatus 32 from accessing selected portions of the host computer 14 or to identify specific lost or stolen accessor apparatus 32.

ART-UNIT: 232

PRIMARY-EXAMINER: Zache; Raulfe B.

ASSISTANT-EXAMINER: Eng; David Y.

ATTY-AGENT-FIRM: Chovanes; Eugene

ABSTRACT:

An access control system for use in connection with a data communication system, particularly a data processing system having a computer apparatus, at least one user terminal and a communication link for providing communication between the computer apparatus and the user terminal is comprised of a controller switch and a first programmed computer means. The controller switch is connected to permit transmission of electrical signals between the computer apparatus and the communication link. The first programmed computer means is connected to the controller switch for actuating the controller switch to connect the computer apparatus and the communication link only upon verification by the first programmed computer that an authorized user is operating the user terminal. The access control system also includes an accessor switch and a second programmed computer means. The accessor switch is connected to permit transmission of electrical signals between the user terminal and the communication link. The second programmed computer means is connected to the accessor switch for actuating the accessor switch to connect the user terminal and the communication link only upon verification by the first programmed computer means that an authorized user is operating the user terminal. The second programmed computer means communicates with the first programmed computer means to verify authorized user operation of the user terminal.

ABSTRACTED-PUB-NO: JP 09327959A

BASIC-ABSTRACT:

The system has a host computer (3) to which a signal is input from a host interface through a net work. An image on the host computer is developed to a frame memory and is directly forwarded to a write in part of a printer (4). the use time of host computer, a font information and the amount of memory used is printed in a billing.

ADVANTAGE - Reduces initial investment. Enables printing of proper values.
